Loan Prediction

The aim of this project is to predict real-estate prices using the machine learning algorithms: Logistic Regression, Decision tree, Random Forest. The three of them will show different results for the accuracy.

Imports

```
import pandas as pd
import requests
import matplotlib.pyplot as plt
import seaborn as sns
from google.colab import files
from datetime import datetime
import io
import mpl_toolkits
import numpy as np
%matplotlib inline

# Load the data
local_file = files.upload()
train_data = io.BytesIO(local_file['results.csv'])
df = pd.read_csv(train_data)
Choose Files results.csv
```

• **results.csv**(application/vnd.ms-excel) - 104433 bytes, last modified: 4/12/2021 - 100% done Saving results.csv to results (1).csv

Preparing the data for training the models

Encoding to numeric data in order to start the training of the models.

```
#drop the uniques loan id
df.drop('Loan_ID', axis = 1, inplace = True)
df.drop('Unnamed: 0', axis = 1, inplace = True)
```

df.info()

```
<class 'pandas.core.frame.DataFrame'>

Train-Test Split dataset

Heatmaps are very useful to find relations between two variables in a dataset and this way the user gets a visualisation of the numeric data. No correlations are extremely high. Each square shows the correlation between the variables on each axis.

• The correlations between the feautures can be explained:

The close to 1 the correlation is the more positively correlated they are; that is as one increases so does the other and the closer to 1 the stronger this relationship is. It is noticable that the correlation between the ApplicantIncome and LoanAmount is 0.57, which mean that they have a positive correlation, but not strong.

```
om pandas import DataFrame
atplotlib inline
t.figure(figsize=(12, 8))
_temp = df.copy()
dex= ['Gender', 'Married', 'Dependents', 'Education', 'Self_Employed', 'ApplicantIncome',
ls = ['Gender', 'Married', 'Dependents', 'Education', 'Self_Employed', 'ApplicantIncome',
_temp = DataFrame(abs(np.random.randn(12, 12)), index=Index, columns=Cols)
s.heatmap(df_temp.corr(), annot=True, cmap = 'magma')
t.show()
```

Importing sklearn libraries

```
from sklearn.model_selection import train_test_split
from sklearn.tree import DecisionTreeClassifier
from sklearn.ensemble import RandomForestClassifier
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import f1_score
```

Splitting into train and test set after choosing the right features X and labels y

```
y = df['Loan_Status']
X = df.drop('Loan_Status', axis = 1)
```

To split the dataset, I will use random sampling with 80/20 train-test split; that is, 80% of the dataset will be used for training and set aside 20% for testing:

Analyzing the numeric features.

Modeling:

Three models will be built and evaluated by their performances with R-squared metric. Additionally, insights on the features that are strong predictors of house prices, will be analised.

Logistic Regression

```
https://scikit-learn.org/stable/modules/linear_model.html#logistic-regression
extra_warning_msg=_LOGISTIC_SOLVER_CONVERGENCE_MSG)
0.8869565217391304
```

Reporting the coefficient value for each feature. Notice that the coefficients are both positive and negative. The positive scores indicate a feature that predicts class 1, whereas the negative scores indicate a feature that predicts class 0.

The importance of a feature is measured by calculating the increase in the model's prediction error after permuting the feature. A feature is "important" if shuffling its values increases the model error, because in this case the model relied on the feature for the prediction.

```
# get importance
importance = model.coef_[0]
# summarize feature importance
for i,v in enumerate(importance):
   print('Feature: %0d, Score: %.5f' % (i,v))
# plot feature importance
plt.bar([x for x in range(len(importance))], importance)
plt.show()
```

```
Feature: 0, Score: -0.03256
Feature: 1, Score: 0.51781
Feature: 2, Score: 0.00937
```

This might mean that your model is underfit (not enough iteration and it has not used the feature enough) or that the feature is not good and you can try removing it to improve final quality.

```
reature: 9, Score: -1.56869
```

Decision tree:

- 1. Creating classifier
- 2. Fitting classifier with train data

Do predictions on a test set. **Testing** the model by testing the test data.

Evaluate classifier measures accuracy.

Random forests

```
# Feature Scaling
from sklearn.preprocessing import StandardScaler
from sklearn.ensemble import RandomForestRegressor
from sklearn.model selection import cross val score, train test split, GridSearchCV
sc = StandardScaler()
X train = sc.fit transform(X train)
X test = sc.transform(X test)
regressor = RandomForestRegressor(n_estimators=20, random_state=0)
regressor.fit(X train, y train)
y pred = regressor.predict(X test)
from sklearn import metrics
print('Mean Absolute Error:', metrics.mean absolute error(y test, y pred))
print('Mean Squared Error:', metrics.mean squared error(y test, y pred))
print('Root Mean Squared Error:', np.sqrt(metrics.mean squared error(y test, y pred)))
     Mean Absolute Error: 0.2370558375634518
     Mean Squared Error: 0.12299492385786802
     Root Mean Squared Error: 0.35070632138281743
# Import the model we are using

# map feature importance values to the features
feature_importances = zip(importance, X.columns)

#list(feature_importances)
sorted_feature_importances = sorted(feature_importances, reverse = True)

#print(sorted_feature_importances)
top_15_predictors = sorted_feature_importances[0:15]
values = [value for value, predictors in top_15_predictors]
predictors = [predictors for value, predictors in top_15_predictors]
print(predictors)

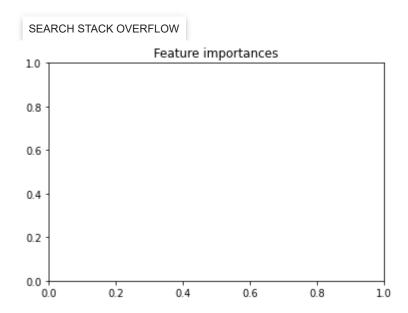

['ApplicantIncome', 'Credit_History', 'LoanAmount', 'LoanAmount_log', 'TotalIncome', 'TotalIncome',
```

Conclusion

From the Modelling, it can be concluded:

- After the exploring of different types of modelling, that the more accurate model is Logistic Regression than Decision tree.
- 2. From the evaluation of the three models, it can be noticed that the Random forest performed better than others

ValueError: shape mismatch: objects cannot be broadcast to a single shape
